

Components:

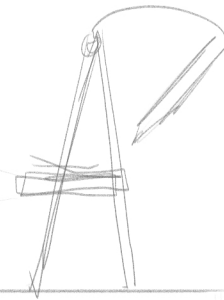

- raspberry pi (could go the LattePanda for more expensive route)
- Lidar or Camera module
- Touch screen
- stylus
- Battery

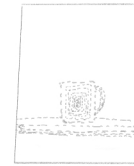

- Vibrating pen
- 1) The pen will vibrate (give a small pulse) to indicate direction for the user on where to (or not to) draw

- 2) This can also be applied through the pen changing colors to indicate "temperature" or how close or far a user's stroke could be.

- 3) Based on the lidar data and user prompted goal the "AI underlayer" can provide opaque suggestive strokes

Lidar

Proximity will be displayed with cluster of dots;
Closer dots mean closer features
faster
downside: just silhouettes

Camera

- more precise but needs image classifier
- slower
- more object detail and can utilize colored pixels
- more computationally heavy
